$\lambda$  in C++

Closure Object

Parameters

Capture

Examples

Curry Function

Generic  $\lambda$

- A Callable Entity is an object that
  - Can be called using the function call syntax
  - Supports operator()
- Such objects are often called
  - A Function Object or
  - A Functor

**Some authors do distinguish between Callable Entities, Function Objects and Functors.**

# Several Callable Entities C++

Functors in STL

### $\lambda$ in C++

Closure Object

Parameters

Capture

Examples

Curry Function

Generic  $\lambda$

- Define a Function Pointer

```
int (*pt2Function) (int, char, char);
```

- Calling Convention

```
int DoIt (int a, char b, char c);
```

```
int DoIt (int a, char b, char c) { printf ("DoIt\n"); return a+b+c; }
```

- Assign Address to a Function Pointer

```
pt2Function = &DoIt; // OR
```

```
pt2Function = DoIt;
```

- Compare Function Pointers

```
if (pt2Function == &DoIt) { printf ("pointer points to DoIt\n"); }
```

- Call the Function pointed by the Function Pointer

```
int result = (*pt2Function) (12, 'a', 'b');
```

# Function Pointers in C

Issues

FCO

Basic Functor

Elementary Example

Functors in STL

### $\lambda$ in C++

Closure Object

Parameters

Capture

Examples

Curry Function

### Generic $\lambda$

## Direct Function Pointer

```
#include <stdio.h>

// Function pointer variable
int (*pt2Function) (int, char, char);

int DoIt(int a, char b, char c);

int main() { pt2Function = DoIt; // &DoIt

    // Paran's needed as operator() has higher
    // precedence than operator*
    int result = (*pt2Function)(12, 'a', 'b');

    printf("%d", result);
}

int DoIt(int a, char b, char c) {
    printf ("DoIt\n"); return a + b + c;
}

---
DoIt
207
```

## Using typedef

```
#include <stdio.h>

// Function pointer type alias
typedef int (*pt2Function) (int, char, char);

int DoIt(int a, char b, char c);

int main() { pt2Function f = &DoIt; // DoIt

    int result = f(12, 'a', 'b');

    printf("%d", result);
}

int DoIt(int a, char b, char c) {
    printf ("DoIt\n"); return a + b + c;
}

---
DoIt
207
```

# Function Reference In C++

### $\lambda$ in C++

Closure Object

Parameters

Capture

Examples

Curry Function

Generic  $\lambda$

- Define a Function Pointer

```
int (A::*pt2Member)(float, char, char);
```

- Calling Convention

```
class A {  
    int DoIt (float a, char b, char c) {  
        cout << "A::DoIt" << endl; return a+b+c;  
    }  
};
```

- Assign Address to a Function Pointer

```
pt2Member = &A::DoIt;
```

- Compare Function Pointers

```
if (pt2Member == &A::DoIt) { cout <<"pointer points to A::DoIt" << endl; }
```

- Call the Function pointed by the Function Pointer

```
int result = (*this.*pt2Member)(12, 'a', 'b');
```

Curry Function

Generic  $\lambda$

## Solution Using switch

```
#include<iostream>
using namespace std;
// The four arithmetic operations
float Plus (float a, float b) { return a+b ; }
float Minus (float a, float b) { return a-b ; }
float Multiply(float a, float b) { return a*b; }
float Divide (float a, float b) { return a/b ; }
void Switch(float a, float b, char opCode) {
    float result;
    Switch(opCode) { // execute operation
        case '+': result = Plus(a, b); break;
        case '-': result = Minus(a, b); break;
        case '*': result = Multiply(a, b); break;
        case '/': result = Divide(a, b); break;
    }
    cout << "Result of = " << result << endl;
}
int main() { float a = 10.5, b = 2.5 ;
    Switch(a, b, '+');
    Switch(a, b, '-');
    Switch(a, b, '*');
    Switch(a, b, '/');
}
```

## Solution Using Function Pointer

```
#include<iostream>
using namespace std;
// The four arithmetic operations
float Plus (float a, float b)
    { return a+b; }
float Minus (float a, float b)
    { return a-b; }
float Multiply(float a, float b)
    { return a*b; }
float Divide (float a, float b)
    { return a/b; }
// Solution with Function pointer
void Switch(float a, float b,
    float (*pt2Func)(float, float)) {
    float result = pt2Func(a, b);
    cout << "Result := " << result << endl;
}
int main() { float a = 10.5, b = 2.5 ;
    Switch(a, b, &Plus);
    Switch(a, b, &Minus);
    Switch(a, b, &Multiply);
    Switch(a, b, &Divide);
}
```

Examples

Curry Function

Generic  $\lambda$

- Smart Functions
  - Functors are functions with a state
  - Functors encapsulate C / C++ function pointers
    - ▷ Uses templates and
    - ▷ Engages polymorphism
- Has its own Type
  - A class with zero or more private members to store the state and an overloaded `operator()` to execute the function
- Usually faster than ordinary Functions
- Can be used to implement callbacks
- Provides the basis for *Command Design Pattern*
- Functor is a first-class object

FCO

Basic Functor

Elementary Example

Functors in STL

$\lambda$  in C++

Closure Object

Parameters

Capture

Examples

Curry Function

Generic  $\lambda$

- Function objects are objects specifically designed to be used with a syntax similar to that of functions. In C++, this is achieved by defining member function operator() in their class, like for example:

```
struct myclass {  
    int operator()(int a) { return a; }  
} myobject;
```

```
int x = myobject (0);    // function-like syntax with object myobject
```

They are typically used as arguments to functions, such as predicates or comparison functions passed to standard algorithms. Several such algorithms are available in STL component:

```
#include <functional>
```

Generic  $\lambda$

- Find the sum of elements in a vector

- Include headers

```
#include <vector>
#include <algorithm> // for_each
#include <functional> // unary_function
```

- User-defined Functor adder with local state

```
struct adder: public
unary_function<double, void> {
    adder() : sum(0)
    double sum;
    void operator()(double x) { sum += x; }
};

vector<double> V;
...
adder result = for_each(V.begin(), V.end(), adder());
cout << "The sum is " << result.sum << endl;
```

$\lambda$  in C++

Closure Object

Parameters

Capture

Examples

Curry Function

Generic  $\lambda$

- Consider the  $\lambda$ -expression: *define*  $\text{rem} \equiv \mathcal{E} \vdash n : \text{Int}, \lambda(m : \text{Int}). m \% n : \text{Int}$ , where
  - $\lambda$  variable  $m$  (type  $\text{Int}$ ) is the *parameter* and is *bound* in *rem*
  - $n$  (type  $\text{Int}$ ) is *free* in *rem* and set from the *environment (context)*  $\mathcal{E}$
  - rem* computes  $m \% n$ , that is,  $m$  modulo  $n$ . It has type  $\text{Int}$  (return type)
- To write *rem* in the *Imperative & OO paradigm of C++*, we define a function / functor:

```
int rem(int m) // Function
    { return m % n; }
// Uses n in context
```

```
struct remainder {           // Functor
    int mod;                 // State
    remainder(int n): mod(n) { } // Ctor (n from context)
    int operator()(int m)     // Function call operator
    { return m % mod; }       // Body
};
```

$\lambda$  Environment:  $\mathcal{E} \vdash n \implies$  Imperative Context:  $\text{int } n; n = 7;$

```
rem(23); // 2
```

```
struct remainder rem(n);
rem(23); // 2
```

```
 $\lambda$ : auto rem = [n](int m) -> int { return m % n; } // Captures n from context
rem(23); // 2
```

- Note that  $[n]$  **Captures**  $n$  from context to close *rem* and create the **Closure Object** in C++

### $\lambda$ in C++

Closure Object

Parameters

Capture

Examples

Curry Function

Generic  $\lambda$

- C++11 introduced  $\lambda$ 's as syntactically lightweight way to define functions on-the-fly
- $\lambda$ 's can *capture* (or close over) variables from the surrounding scope – by *value* or by *reference*
- First consider callable things that do not capture any variables. C++ offers three alternatives:

- **plain functions** (All versions of C & C++)
- **functor classes** (C++03 onwards), and
- **lambdas** (C++11 onwards)

```
#include <iostream> // cout
using namespace std;
```

```
int function (int a) { return a + 3; }
class Functor { public: int operator()(int a) { return a + 3; } };
auto lambda = [] (int a) { return a + 3; };
```

```
int main() { Functor functor;
    cout << function(5) << ' ' << functor(5) << ' ' << lambda(5) << endl;
}
8 8 8
```

- For plain functions that capture no variables, lambdas and functors behave the same

Virtual Function

Callback

Issues

FCO

Basic Functor

Elementary Example

Functors in STL

### $\lambda$ in C++

Closure Object

Parameters

Capture

Examples

Curry Function

### Generic $\lambda$

- A  $\lambda$  expression consists of the following:

```
[capture list] (parameter list) -> return-type { function body }
```

- The capture list and parameter list can be empty, so the following is a valid  $\lambda$ :

```
[] () { cout << "Hello, world!" << endl; }
```

- *Parameter list* is a sequence of parameter types and variable names as for an ordinary function
- *Function body* is like an ordinary function body
- If the *function body* has only one return statement (which is very common), the *return type* is assumed to be the same as the type of the value being returned
- If there is *no return statement* in the function body, the return type is assumed to be `void`

- Below  $\lambda$  has return type `void` – can be called without any use of the return value:

```
[] () { cout << "Hello from trivial lambda!" << endl; } ();
```

- However, trying to use the return type of the call is an error:

```
cout << [] () { cout << "Hello from trivial lambda!" << endl; } () << endl;
```

### $\lambda$ in C++

Closure Object

Parameters

Capture

Examples

Curry Function

Generic  $\lambda$

- Below  $\lambda$  returns a `bool` value which is true if the first param is half of the second. The compiler knows the return type as `bool` from the return statement:

```
if ([](int i, int j) { return 2 * i == j; } (12, 24))  
    cout << "It's true!";  
else  
    cout << "It's false!";
```

- To specify return type:

```
cout << "This lambda returns " << [](int x, int y) -> int  
{  
    if(x > 5) return x + y;  
    else  
        if (y < 2) return x - y; else return x * y;  
} (4, 3) << endl;
```

- Below  $\lambda$ , returns an `int`, though the return statement provides a `double`:

```
cout << "This lambda returns " <<  
    [](double x, double y) -> int { return x + y; } (3.14, 2.7) << endl;
```

The output is "This lambda returns 5"

FCO

Basic Functor

Elementary Example

Functors in STL

### $\lambda$ in C++

Closure Object

Parameters

Capture

Examples

Curry Function

Generic  $\lambda$

- Below  $\lambda$  *captures n by value* to compute the value of remainder of  $m$ :

```
int n = 7;
```

```
auto rem = [n](int m) -> int { return m % n; };
```

- $n$  is captured by  $[n]$  (value – a copy is made from the context) at the time of constructing the closure object. Hence  $n$  *must be initialized before the construction* of the closure
- The *value of n cannot be changed* within the  $\lambda$  (for immutable  $\lambda$ 's)
- The changes to  $n$  after the construction of the closure object are not reflected

- Below  $\lambda$  *captures s by reference* to accumulate the value of  $m$ :

```
int s = 0;
```

```
auto acc = [&s](int m){ s += m; };
```

- $s$  is captured by  $[&s]$  (reference – a reference is set to the context) at the time of constructing the closure object. Hence it is *optional to initialize s before the construction* of the closure. However, it must be initialized before the use of the closure
- The *value of s can be changed* within the  $\lambda$
- The changes to  $s$  after the construction of the closure object will be reflected

Issues

FCO

Basic Functor

Elementary Example

Functors in STL

### $\lambda$ in C++

Closure Object

Parameters

Capture

Examples

Curry Function

Generic  $\lambda$

- **Closure**

- A *closure* (*lexical* / *function closure*), is a technique for implementing *lexically scoped name binding* in a language with first-class functions
- Operationally, a closure is a *record storing a function* together with an *environment*
- The *environment* is a mapping associating (*binding*) each *free* variable of the function with the *value* or *reference* to which the name was bound when the closure was created
- *Unlike a plain function, a closure allows the function to access captured variables through the closure's copies of their values or references, even in its invocations outside their scope*

- **Lambdas vs. Closures** (From *Lambdas vs. Closures* by Scott Meyers, 2013)

- A  $\lambda$  expression `auto f = [&](int x, int y){ return fudgeFactor * (x + y); }` *exists only in a program's source code*. A lambda *does not exist at runtime*
- The runtime effect of a  $\lambda$  expression is the generation of an object, called *closure*
- Note that *f* is not the closure, it is a *copy of the closure*. The *actual closure object is a temporary* that's typically destroyed at the end of the statement
- Each  $\lambda$  expression causes a unique class to be generated (during compilation) and also causes an object of that class type – a closure – to be created (at runtime)
- Hence, *closures are to lambdas as objects are to classes*

### $\lambda$ in C++

Closure Object

Parameters

Capture

Examples

Curry Function

### Generic $\lambda$

- A  **$\lambda$ -expression** generates a **Closure Object** at *run-time*
- A closure object is *temporary*
- A closure object is *unnamed*
- For a  $\lambda$ -expression, the compiler creates a *functor class* with:
  - *data members*:
    - ▷ a value member each for each value capture
    - ▷ a reference member each for each reference capture
  - a *constructor* with the captured variables as parameters
    - ▷ a value parameter each for each value capture
    - ▷ a reference parameter each for each reference capture
  - a *public inline const function call operator()* with the parameters of the lambda as parameters, generated from the body of the lambda
  - *copy constructor*, *copy assignment operator*, and *destructor*
- A *closure object* is constructed as an instance of this class and *behaves like a function object*
- A  $\lambda$ -expression without any capture behaves like a function pointer

$\lambda$  in C++

Closure Object

Parameters

Capture

Examples

Curry Function

Generic  $\lambda$

- The *captures* is a comma-separated list of zero or more captures, optionally with default
- The capture list defines the outside variables that are accessible from the  $\lambda$  function body
- The only capture defaults are
  - `[&]` (implicitly capture the used automatic variables *by reference*) and
  - `[=]` (implicitly capture the used automatic variables *by copy / value*)
- The *current object* (`*this`) can be *implicitly captured* if either capture default is present
- If implicitly captured, it is always captured by reference, even for `[=]`. Deprecated since C++20

Capture	Meaning	C++
<code>identifier</code>	simple by-copy capture	C++11
<code>identifier ...</code>	simple by-copy capture that is a <i>pack expansion</i>	C++11
<code>identifier init</code>	by-copy capture with an <i>initializer</i>	C++14
<code>&amp; identifier</code>	simple by-reference capture	C++11
<code>&amp; identifier ...</code>	simple by-reference capture that is a <i>pack expansion</i>	C++11
<code>&amp; identifier init</code>	by-reference capture with an <i>initializer</i>	C++14
<code>this</code>	simple by-reference capture of the current object	C++11
<code>*this</code>	simple by-copy capture of the current object	C++17
<code>... identifier init</code>	by-copy capture with an <i>initializer</i> that is a <i>pack expansion</i>	C++20
<code>&amp; ... identifier init</code>	by-reference capture with an <i>initializer</i> that is a <i>pack expansion</i>	C++20

### λ in C++

Closure Object

Parameters

Capture

Examples

Curry Function

Generic λ

## Wrong Capture by Reference

- Closures may outlive their creating function

```
std::function<bool(int)>
returnClosure(int a) { // returns bool
    int b, c;
    ...
    // won't compile, but assume it would
    return [](int x)
        { return a*x*x + b*x + c == 0; };
}
```

```
// f is essentially a copy of
// lambda's closure
auto f = returnClosure(10);
```

```
...
if (f(22)) // invoke the closure
```

- What are the values of **a**, **b**, **c** in the call?
  - `returnClosure` no longer active!
- Non-static locals referenceable only if **captured**

## Correct Capture by Reference

- This version has no such problem

```
int a; // now at global or namespace scope
std::function<bool(int)>
returnClosure() {
    static int b, c; // now static ...
```

```
// now compiles
return [](int x)
    { return a*x*x + b*x + c == 0; };
}
```

```
// as before
```

```
auto f = returnClosure();
...
if (f(22)) // as before
```

- a**, **b**, **c** outlive `returnClosure`'s invocation
- Variables of static storage duration always referenceable

### $\lambda$ in C++

Closure Object

Parameters

Capture

Examples

Curry Function

Generic  $\lambda$

- Consider

```
int h = 10;  
auto two_h = [=] () { h *= 2; return h; };  
std::cout << "2h:" << two_h() << " h:" << h << std::endl;
```

error C3491: 'h': a by-value capture cannot be modified in a non-mutable lambda

- $\lambda$  closure objects have a *public inline function call operator* that:
  - Matches the parameters of the lambda expression
  - Matches the return type of the lambda expression
  - Is declared `const`

- Make mutable*

```
int h = 10;  
auto two_h = [=] () mutable { h *= 2; return h; };  
std::cout << "2h:" << two_h() << " h:" << h << std::endl;
```

2h:20 h:10

Virtual Function

Callback

Issues

FCO

Basic Functor

Elementary Example

Functors in STL

### $\lambda$ in C++

Closure Object

Parameters

Capture

Examples

Curry Function

### Generic $\lambda$

- Will this compile? If so, what is the result?

```
struct foo {  
    foo() : i(0) { }  
    void amazing(){ [=]{ i = 8; }(); } // i is captured by value  
                                        // Can it be changed without mutable?  
  
    int i;  
};  
foo f;  
f.amazing();  
std::cout << "f.i : " << f.i;
```

Output: f.i : 8

- this** implicitly captured
- i** actually is **this->i** which can be written from a member function as a data member.  
So no **mutable** is required

# [=, &identifier]() -> rt{...}: Capture

Functors in STL

### λ in C++

Closure Object

Parameters

Capture

Examples

Curry Function

### Generic λ

```
class A { std::vector<int> values; int m_;  
public: A(int mod) : m_(mod) { }  
    A& put(int v) { values.push_back(v); return *this; }  
    int extras() { int count = 0;  
        std::for_each(values.begin(), values.end(),  
            [=, &count](int v){ count += v % m_; });  
        return count;  
    }  
};  
A g(4);  
g.put(3).put(7).put(8);  
std::cout << "extras: " << g.extras();
```

extras: 6

- Capture default by value
- Capture `count` by reference, accumulate, return
- How do we get `m_`?
- Implicit capture of `'this'` by value

$\lambda$  in C++

Closure Object

Parameters

Capture

Examples

Curry Function

Generic  $\lambda$

- Capture restrictions

- Identifiers must only be listed once

```
[i,j,&z]() {...} // Okay
```

```
[&a,b]() {...} // Okay
```

```
[z,&i,z]() {...} // Bad, z listed twice
```

- Default by value, explicit identifiers by reference

```
[=,&j,&z]() {...} // Okay
```

```
[=,this]() {...} // Bad, no this with default =
```

```
[=,&i,z]() {...} // Bad, z by value
```

- Default by reference, explicit identifiers by value

```
[&,j,z]() {...} // Okay
```

```
[&,this]() {...} // Okay
```

```
[&,i,&z]() {...} // Bad, z by reference
```

- Scope of Capture

- Captured entity must be defined or captured in the immediate enclosing lambda expression or function

# function<R(Args...)>

Closure Object  
Parameters  
Capture  
Examples  
Curry Function  
Generic  $\lambda$

- **Function pointers**

```
int my_free_function(std::string s) { return s.size(); }  
std::function< int(std::string) > f = my_free_function;  
int size = f("ppd");
```

- **Functors**

```
struct my_functor { std::string s_; my_functor(std::string const & s) : s_(s) { }  
    int operator()() const { return s_.size(); }  
};  
my_functor mine("ppd");  
std::function< int() > f = std::ref(mine);  
int size = f();
```

- **Closure Objects**

```
std::function< int(std::string const &) > f = [](std::string const & s){ return s.size(); };  
int size = f("ppd");
```

- **Member function pointers**

```
struct my_struct { std::string s_; my_struct(std::string const & s) : s_(s) { }  
    int size() const { return s_.size(); }  
};  
my_struct mine("ppd");  
std::function< int() > f = std::bind(&my_struct::size, std::ref(mine));  
int size = f();
```

Issues

FCO

Basic Functor

Elementary Example

Functors in STL

### $\lambda$ in C++

Closure Object

Parameters

Capture

Examples

Curry Function

### Generic $\lambda$

```
#include <iostream>    // std::cout
#include <functional>

int main() {
    auto add = [](int x, int y) { return x + y; };
    auto add5 = [=](int y) { return add(5, y); }; // Curry

    std::cout << "W/o curry:\n" << add(5, 3);
    std::cout << "W/  curry:\n" << add5(3);
}
```

Output:

W/o curry:8

W/ curry:8

- On the 'Curry' line, we can capture also by `[&]`, `[&add]`, or `[add]`. However, it does not work without default or explicit capture as the symbol `add` is used in the body. So `[]` fails
- This is a hard-coded solution. There is built-in solution. Generic operator for Curry can be built separately using variadic templates, variadic functions and lambda functions. This is outside of our current scope.

### $\lambda$ in C++

Closure Object

Parameters

Capture

Examples

Curry Function

### Generic $\lambda$

- C++11 introduced  $\lambda$  expressions as short inline anonymous functions that can be nested inside other functions and function calls
- C++ 14 buffed up  $\lambda$  expressions by introducing Generic or Generalized  $\lambda$
- Following  $\lambda$  function returns the sum of two integers

```
[] (int a, int b) -> int { return a + b; } // Return type is optional
```

- Whereas we need a different  $\lambda$  to obtain the sum of two floating point values:

```
[] (double a, double b) -> double { return a + b; } // Return type is optional
```

- In C++11 we could unify these two  $\lambda$  functions using template parameters:

```
template<typename T>
[] (T a, T b) -> T { return a + b } // Return type is optional - compiler may infer
```

- C++ 14 circumvent this by the keyword `auto` in the input parameters of the  $\lambda$  expression. Thus the compilers can now deduce the type of parameters during compile time:

```
[] (auto a, auto b) { return a + b; } // Compiler must infer return type
```

### Generic $\lambda$

```
#include <iostream>, #include <string>, using namespace std;
```

```
// C++11 lambda's - separate lambda for every type. Return type is optional
```

```
auto add_i = [](int a, int b) { return a + b; }; // Compiler may infer return type
```

```
auto add_d = [](double a, double b) { return a + b; }; // Compiler may infer return type
```

```
auto add_s = [](string a, string b) { return a + b; }; // Compiler may infer return type
```

```
// C++11 templated lambda - one lambda for multiple types. Return type is optional
```

```
template<typename T> auto add_t = [](T a, T b) { return a + b; }; // Compiler may infer return type
```

```
// C++14 generic lambda. Return type cannot be specified
```

```
auto add = [](auto a, auto b) { return a + b; }; // Compiler must infer return type
```

```
int main () {
```

```
    // Different name of each lambda for each type: No inference
```

```
    cout << add_i(3, 5); // add_i for int type
```

```
    cout << add_d(2.6, 1.3); // add_d for double type
```

```
    cout << add_s("Good ", "Day"); // add_s for string type converts from const char*
```

```
    // Same name of the lambda for all types, type must be specified: No inference
```

```
    cout << add_t<int>(3, 5); // add_t<int> for int type
```

```
    cout << add_t<double>(2.6, 1.3); // add_t<double> for double type
```

```
    cout << add_t<string>("Good ", "Day"); // add_t<string> for string type converts from const char*
```

```
    // Same name of the lambda for all types and no type need to be specified: It is inferred
```

```
    cout << add(3, 5); // add for int type
```

```
    cout << add(2.6, 1.3); // add for double type
```

```
    cout << add(string("Good "), string("Day")); // add for string type - cannot convert from const char*
```

## $\lambda$ in C++

Closure Object

Parameters

Capture

Examples

Curry Function

## Generic $\lambda$

- The return type may be inferred by the compiler from the return expression:

```
auto add = [](auto a, auto b) { return a + b; };  
cout << add(2, 3);           // 5 // rt = int  
cout << add(4, 3.3);         // 7.3 // rt = double  
cout << add(2.6, 2);          // 4.6 // rt = double  
cout << add(3.8, 4.5);        // 8.3 // rt = double
```

- The return type may be specified from the parameters:

```
auto add = [](auto a, auto b) -> decltype(a) { return a + b; };  
cout << add(2, 3);           // 5 // rt = int  
cout << add(4, 3.3);         // 7 // rt = int  
cout << add(2.6, 2);          // 4.6 // rt = double  
cout << add(3.8, 4.5);        // 8.3 // rt = double
```

```
auto add = [](auto a, auto b) -> decltype(b) { return a + b; };  
cout << add(2, 3);           // 5 // rt = int  
cout << add(4, 3.3);         // 7.3 // rt = double  
cout << add(2.6, 2);          // 4 // rt = int  
cout << add(3.8, 4.5);        // 8.3 // rt = double
```

- The return type may be explicitly specified:

```
auto add = [](auto a, auto b) -> int { return a + b; };
```

Generic  $\lambda$

- A  $\lambda$  does not have a named specific type. So a recursive  $\lambda$  expression needs `std::function` wrapper
- The generic  $\lambda$  expression allows recursive  $\lambda$  functions without using `std::function`

```
#include <iostream> // C++11 solution using std::function. Works for int base
```

```
#include <functional>
```

```
int main() {
```

```
    std::function<int(int,int)> pow; // pow recursive function. std::function used to define type of pow
```

```
    pow = [&pow](int base, int exp) { return exp==0 ? 1 : base*pow(base, exp-1); };
```

```
    std::cout << pow(2, 10); // 2^10 = 1024
```

```
    std::cout << pow(2.71828, 10); // e^10 = 1024 // 2.71828 is cast to int giving 2 and wrong result
```

```
}
```

```
#include <iostream> // C++14 solution without using std::function. Works for any numeric base
```

```
int main() {
```

```
    auto power = [](auto self, auto base, int exp) -> decltype(base) { // any numeric 'base' type
```

```
        return exp==0 ? 1 : base*self(self, base, exp-1);
```

```
};
```

```
// Wrapper of power to avoid passing power as first parameter to the call
```

```
auto pow = [power](auto base, int exp) -> decltype(base) { return power(power, base, exp); };
```

```
std::cout << power(power, 2, 10); // 2^10 = 1024 // Needs to pass itself as first parameter
```

```
std::cout << power(power, 2.71828, 10); // e^10 = 22026.3
```

```
std::cout << pow(2, 10); // 2^10 = 1024 // Wrapper provides a clean solution
```

```
std::cout << pow(2.71828, 10); // e^10 = 22026.3
```

```
}
```

### Generic $\lambda$

- A non-generic  $\lambda$  with an empty capture-list can be converted to a function pointer

```
typedef int (*fp) (int);           // Function pointer
const fp f = [](int i){ return i; }; // Converts to a func. ptr. w/o capture
```
- A capture-less generic  $\lambda$  behaves in the same way
- Further, it can be converted to more than one compatible function pointers

```
#include <iostream>
```

```
void f(void(*fp)(int))    { fp(1); /*...*/ }
void g(void(*fp)(double)) { fp(2.2); /*...*/ }
```

```
int main () {
    auto op = [](auto x) { // generic code for x
        std::cout << "x = " << x << std::endl;
    };

    // use 'op' as a generic callback function pointer
    f(op); // x = 1
    g(op); // x = 2.2
}
```
